Locators

1

## Outline and Reading

- ◆ Locators (§2.4.4)
- ◆ Locator-based methods (§2.4.4)
- ◆ Implementation
- ◆ Positions vs. Locators

## Locators

- ◆ A locators identifies and tracks a (key, element) item within a data structure
- ◆ A locator sticks with a specific item, even if that element changes its position in the data structure
- ◆ Intuitive notion:
  - claim check
  - reservation number
- ◆ Methods of the locator ADT:
  - `key()`: returns the key of the item associated with the locator
  - `element()`: returns the element of the item associated with the locator
- ◆ Application example:
  - Orders to purchase and sell a given stock are stored in two priority queues (sell orders and buy orders)
    - the key of an order is the price
    - the element is the number of shares
  - When an order is placed, a locator to it is returned
  - Given a locator, an order can be canceled or modified

## Locator-based Methods

- ◆ Locator-based priority queue methods:
  - `insert(k, o)`: inserts the item (k, o) and returns a locator for it
  - `min()`: returns the locator of an item with smallest key
  - `remove(l)`: remove the item with locator l
  - `replaceKey(l, k)`: replaces the key of the item with locator l
  - `replaceElement(l, o)`: replaces with o the element of the item with locator l
- ◆ locator(): returns an iterator over the locators of the items in the priority queue
- ◆ Locator-based dictionary methods:
  - `insert(k, o)`: inserts the item (k, o) and returns its locator
  - `find(k)`: if the dictionary contains an item with key k, returns its locator, else return the special locator NO SUCH KEY
  - `remove(l)`: removes the item with locator l and returns its element
  - `locators(), replaceKey(l, k), replaceElement(l, o)`

## Implementation

- ◆ The locator is an object storing
  - key
  - element
  - position (or rank) of the item in the underlying structure
- ◆ In turn, the position (or array cell) stores the locator
- ◆ Example:
  - binary search tree with locators

## Positions vs. Locators

- ◆ Position
  - represents a "place" in a data structure
  - unrelated to other positions in the data structure (e.g., previous/next or parent/child)
  - implemented as a node or an array cell
- ◆ Position-based ADTs (e.g., sequence and tree) are fundamental data storage schemes
- ◆ Locator
  - identifies and tracks a (key, element) item
  - unrelated to other locators in the data structure
  - implemented as an object storing the item and its position in the underlying structure
- ◆ Key-based ADTs (e.g., priority queue and dictionary) can be augmented with locator-based methods
